

# Applications and extensions of a theorem of Gallai

**Gábor Simonyi**

Rényi Institute, Budapest

In a seminal paper about comparability graphs Gallai proved the following results.

Theorem (Gallai 1967): If the edges of the complete graph  $K_n$  are colored so that no triangle gets **3** different colors, then at most **2** colors span a connected graph on the  $n$  vertices.

To honour this result we call an edge-coloring a **Gallai-coloring** if no triangle gets **3** different colors.

The above Theorem easily implies the following statement.

Corollary (Gallai 1967): A Gallai-colored complete graph can always be obtained from a **2**-edge-colored complete graph by substituting Gallai-colored complete graphs into its vertices.

# Statements expressible in terms of Gallai-colorings

Thm. (Gallai 1967): If a complete graph is Gallai-colored with  $\geq 3$  colors and each of two colors span comparability graphs then so does their union.

Inspired by this result the following theorem was proved.

Thm. (K. Cameron, Edmonds, Lovász 1986): If a complete graph is Gallai-colored and all but one of the colors give perfect graphs, then so does the last color (or equivalently, by the Perfect Graph Theorem: their union).

Thm. (Erdős, Simonovits, T. Sós 1973): If  $K_n$  is Gallai-colored, then at most  $n - 1$  colors can be used.

This result was originally stated in different terms and had a very elegant proof that was independent of Gallai's theorem.

(Assume for contradiction that at least  $n$  colors appear. Select an edge of each color. You have at least  $n$  edges on  $n$  vertices, so there is a cycle which is totally multicolored. Diagonals give shorter multicolored cycles, finally a multicolored triangle.)

But one can also easily prove the statement by using Gallai's theorem and induction on  $n$ .

# Graph entropy

Körner defined graph entropy in 1971 as the solution of a problem in information theory. A later found short definition is this:

$$H(G, P) := \min_{(a_1, \dots, a_n) \in VP(G)} \sum_{i=1}^n p_i \log \frac{1}{a_i},$$

where  $G$  is a graph on  $n$  vertices,  $P = (p_1, \dots, p_n)$  is a probability distribution on its vertex set, and  $VP(G)$  is the vertex packing polytope of  $G$ .

The vertex packing polytope is the set of points in  $\mathbb{R}^n$  that can be expressed as convex combinations of characteristic vectors of stable sets.

In particular,

$$H(K_n, P) = \min_{(q_1, \dots, q_n) \in VP(K_n)} \sum_{i=1}^n p_i \log \frac{1}{q_i} =$$

$$\sum_{i=1}^n p_i \log \frac{1}{p_i} = H(P),$$

the Shannon entropy of the probability distribution  $P$ .

## Subadditivity and additivity

An important property of  $H(G, P)$  is its sub-additivity:

$$H(F \cup G, P) \leq H(F, P) + H(G, P), \text{ where } V(F) = V(G) = V(F \cup G) \text{ and } E(F \cup G) = E(F) \cup E(G).$$

Thm. (Csiszár, Körner, Lovász, Marton, S. 1990)

$$\forall P : H(G, P) + H(\bar{G}, P) = H(P)$$

iff  $G$  is perfect.

Q: What about equality for general (not necessarily complementary)  $F$  and  $G$ ?

Thm. (Körner, S., Tuza 1992): Let  $F$  and  $G$  be two edge-disjoint graphs on the same vertex set  $V$ . We have

$$\forall P : H(F \cup G, P) = H(F, P) + H(G, P)$$

iff the following two conditions are satisfied:

1. If on some  $U \subseteq V$  all edges belong to  $F \cup G$ , then the induced subgraphs  $F[U]$  and  $G[U]$  are perfect.
2. Considering the edges of  $F$ ,  $G$  and the rest as a 3-edge coloring, we get a Gallai-coloring.

Thm. (Körner, S. 2000): Let  $F$  and  $G$  be two graphs with possibly intersecting edge sets on the same vertex set  $V$ . Assume that  $F \cup G = K_{|V|}$ . Then

$$\forall P : H(F \cup G, P) + H(F \cap G, P) \leq H(F, P) + H(G, P)$$

holds iff coloring the edges according to their membership in  $F - G$ ,  $G - F$ , and  $F \cap G$  gives a Gallai-coloring.

Remark: The proof of both of the last two theorems rely on Gallai's theorem, that makes an inductive proof possible and very natural.

## Gallai-colorings generalize 2-colorings

Thm. (Burr, unpublished): Any 2-coloring of a complete graph contains a monochromatic spanning broom.

(Broom: a path with a star on one of its endpoints.)

The Gallai-colored version is the following:

Thm. (Gyárfás, S. 2004): A Gallai-colored complete graph always contains a monochromatic spanning broom.

The proof uses Burr's ideas and Gallai's theorem.

Thm. (Erdős, Fowler 1999): A 2-edge-colored complete graph on  $n$  vertices always contains a monochromatic subgraph of diameter at most 2 with at least  $\lceil 3n/4 \rceil$  vertices.

Thm. (Gyárfás, G. Sárközy, Sebő, Selkow 2010): A Gallai-colored complete graph on  $n$  vertices always contains a monochromatic subgraph of diameter at most 2 with at least  $\lceil 3n/4 \rceil$  vertices.

The GySSS paper cited above gives conditions that make it automatic to obtain the Gallai-colored version of a theorem for 2-colorings. These cover several cases but not all of them.

# Gallai-colorings of non-complete graphs

It is natural to start exploring properties of Gallai-colored graphs that are not necessarily complete, but are edge-colored so, that no tricolored triangle occurs.

Such investigations were initiated by Gyárfás and G. Sárközy, who proved the following result.

Thm. (Gyárfás, G. Sárközy 2010): Let  $G$  be a Gallai-colored graph with independence number  $\alpha$ . Then  $G$  contains a monochromatic component of size at least  $\frac{|V(G)|}{\alpha^2 + \alpha - 1}$ .

For  $G = K_n$  we get that 1 color class spans the whole vertex set. For 2-colorings this is a well-known and easy exercise.

Another result in this direction is the following.

Thm. (Gyárfás, S., Á. Tóth 2012): Let  $G$  be a Gallai-colored graph with independence number  $\alpha$ . Then there is a function  $g : \mathbb{N} \rightarrow \mathbb{N}$  such that the vertices of  $G$  can be covered by  $g(\alpha)$  monochromatic components. If  $\alpha = 2$  then at most 5 components are enough.

Note that for  $\alpha = 2$  the last statement generalizes (the  $\alpha = 2$  special case of) the previous theorem.

A further generalization is the following.

Thm. (Fujita, Furuya, Gyárfás, Á. Tóth 2012): Let  $G$  be a Gallai-colored graph with independence number  $\alpha$ . Then there is a function  $g : \mathbb{N} \rightarrow \mathbb{N}$  such that the vertices of  $G$  can be **partitioned** into  $g(\alpha)$  monochromatic components.

The point is that just eliminating the intersections in a covering (that exists by the previous theorem) may disconnect some of the so far monochromatic components. So this last theorem is stronger than the previous one.

# Gallai-Ramsey numbers

Let  $\text{RG}(r, H)$  denote the minimum  $m$  such that in every Gallai-colored  $K_m$  with  $r$  colors, a monochromatic copy of  $H$  occurs.

A sample theorem:

Thm. (Gyárfás, G. Sárközy, Sebő, Selkow 2010):

For fixed  $H$ ,  $\text{RG}(r, H)$  is exponential in  $r$  if  $H$  is not bipartite; linear in  $r$  if  $H$  is bipartite but not a star; and constant (independent of  $r$ ) if  $H$  is a star.

# Open problems

One of the most interesting open problems seems to be this:

Give necessary and sufficient conditions for a true statement about 2-edge-colored complete graphs to be “automatically” true for Gallai-colored complete graphs.

Another problem is the missing cases of properties of graph entropy. In particular, when is it true for all prob. dist.  $P$  that

$$H(F \cup G, P) + H(F \cap G, P) \leq H(F, P) + H(G, P)?$$
